**Educational Testing Service
Revised, February 2009**

Forward

The technical information included in this report is intended for use by those who evaluate tests, interpret scores, or use test results in making educational decisions. It is assumed that the reader has some technical knowledge of test construction and measurement procedures, as stated in Standards of Educational and Psychological Testing (American Educational Research Association, American Psychological Association, National Council on Measurement in Education, 1999).

Introduction

The Maryland High School Assessments (HSAs) consist of end-of-course tests in Algebra/Data Analysis, Biology, English, and Government. The HSAs are referred to as “end-of-course” tests because students take each test when they complete the appropriate coursework.

Students who entered 9th grade in the 2005-2006 school year or subsequent school years are required to earn satisfactory scores on all four content areas measured by the HSAs or Modified High School Assessments (Mod-HSAs) in order to earn a Maryland High School Diploma¹. Results from the Algebra, Biology and English administrations are used in the MSDE Adequate Yearly Progress (AYP) reports, required under the No Child Left Behind Act (NCLB). Information on the interpretation of scores is provided to students, parents, schools and other stakeholders via the Maryland State Department of Education (MSDE) website

Starting in May 2008, MSDE test administrations include the Mod-HSAs. The Mod-HSAs are a modified version of the HSAs; they are designed for special education students with Individualized Education Programs (IEPs). The Mod-HSAs may be taken in place of one or more of the HSAs. Eligibility to take the Mod-HSAs will be determined by a student’s IEP and evidence of progress in learning course content.

The Mod-HSAs assess the same skills as the HSAs. Mod-HSA items were derived from banked HSA items, but the question format was simplified. For example, the Mod-HSA assessments contain selected response (SR) items only, the SR items have three answer options instead of four, and the items have reduced reading load and simplified graphics. All items are based on content outlined in Maryland’s Core Learning Goals (CLGs).

Mod-HSA forms are designed to provide a total test score and a subscore for each reporting category. They are administered both online and in paper format. The eventual goal is to have most students test online, with only special forms (Braille, KurzweilTM, and Large Print) administered on paper.

Development of Mod-HSA Test Forms

Two Mod-HSA field test forms per content area were developed for a May 2008 administration. Of the items administered, 50 subsequently were selected to comprise each of two pre-equated operational forms that would be used to score students participating in this administration and to comprise forms to be used in subsequent administrations.

¹ More information on state graduation requirements is available on the Maryland State Department of Education Web site at <http://www.marylandpublicschools.org/MSDE/testing/hsa/>.

The field test forms contained 94 to 99 items each. Each form included 70 to 75 modified-HSA field test items that differed across the forms and a set of 24 common HSA items designed to serve as an external anchor for linking purposes. The 24-item external anchor was used to link the Mod-HSA items to the HSA scale and did not count toward students' final scores.

In May; Form 108 was administered on paper and online, Form 208 was administered online only. There was also a Summer administration, and two forms were administered for each content area. Form 308 served as the primary form and was administered online and, as an accommodation, on paper; Form 408 served as a make-up form and was administered online.

Following item analyses, calibration, and linking, the 50-item operational forms were selected by MSDE to comprise each operational form. These forms were used to score the present and future administrations. The item parameters estimated during the May 2008 administration are used to generate scores on these forms, so no calibration or equating will be needed in future administrations.

In the future, the operational Mod-HSAs will be administered at the same time as the HSA, that is, in each October, January, April, May, and Summer (July/August).

Description of Target Groups and Linking Samples

To obtain data that could be used to link the Mod-HSA to the HSA scale, two groups of students took the Mod-HSA in May 2008. The first group was the *Target* population, which were students identified by MSDE as being eligible to take the Mod-HSAs. These students took the Mod-HSA instead of the regular HSA. The second group of students was the *Linking* sample, which consisted of regular HSA examinees identified by MSDE to take the Mod-HSA in the same content area as their May HSA. The data provided by this second group of examinees were used to calibrate the Mod-HSA field test forms and to equate these forms. As an incentive to participate in the Linking sample, these HSA students received the higher of their two scores on the Mod-HSA and regular HSA.

Students from the Target population, taking the paper version of the Mod-HSA, took Form 108, while Forms 108 and 208 were spiraled at the school level for the students taking the online version of the test. For the Target population, data resulting from the paper and online versions of the Mod-HSAs were combined for the analyses of Form 108 described in this report.

All students in the Linking sample took Form 108 or 208 of the Mod-HSAs online. The forms were spiraled at the school level to ensure that a comparable number of students took each form.

Equating Designs

Two equating designs were used to align scores from the Mod-HSAs to the same scale as the HSAs: 1) common items design, and 2) common persons design. The common items design made use of the external HSA anchor sets embedded in the Mod-HSAs. The common persons design used the HSA and Mod-HSA scores of the Linking sample for the equating. The two designs were planned so that if one design was not effective, there would be an alternative approach that might be used for the purposes of aligning the Mod-HSAs to the HSA scale. These designs are explained further in Section 4 of this report.

Organization of the Technical Report

This technical report contains seven Sections and four Appendices.

- Section 1 describes test development, form construction and administration details;
- Section 2 discusses the validity of the Mod-HSAs;
- Section 3 describes the item-level analyses conducted to provide information for selection of the 50-item operational forms for each content area;
- Section 4 presents item response theory calibration and scaling information;
- Section 5 describes the scoring procedures;
- Section 6 provides information related to the test characteristics;
- Section 7 presents information regarding student characteristics.

The appendices contain more detailed statistical results. Appendix A provides classical item statistics for the 50-item operational forms, for both the Target population and the Linking samples in the May administration, and for the Target population in the Summer administration. Appendix B provides classical item statistics of the field test items, for the Linking samples, by form. Appendix C presents a comparison of the results of the two equating methods used during the May administration, including summary statistics, test characteristic curves (TCCs) and conditional standard errors of measurement (CSEMs). Appendix D provides histograms of the scale score distributions by content area and by group for the May 2008 administration.

All technical support and analyses were carried out in accordance with both the *Educational Testing Service Standards for Quality and Fairness* (2002) and the *Standards for Educational and Psychological Testing*, issued jointly by the American Educational Research Association, American Psychological Association, and National Council on Measurement in Education (1999).

Section 1. Test Construction and Administration

Test Development

Planning

Planning for the test development process began with the creation of the Mod-HSA blueprints and item modification/development plans for each content area. MSDE content specialists collaborated with Maryland educators, both special education and content area experts, to develop a plan for modifying and developing content for the modified assessments. The HSA item bank was reviewed to determine how well the available item pool could be modified to meet the item requirements of the Mod-HSAs and blueprint requirements as identified across the CLGs. Items, passages, and stimuli identified as modifiable were revised according to item plans, using such modifications as reducing the number of response options from 4 to 3, the simplification of language and graphics, grouping of text within longer passages, and the repetition of critical passage text within an item. When deficits in the pool of modifiable items were identified, additional items were developed by MSDE and its collaborative partners.

Test Specifications and Design

The basic test design was defined by MSDE and provided to Educational Testing Service (ETS).

As noted in the Introduction, two Mod-HSA forms per content area were developed for the May 2008 administration. Each field test form contained 94 to 99 items each. The forms included two comparable 50-item sets of items designed to meet the content requirements for the future operational Mod-HSA forms. In addition, sets of 20 to 25 additional items were included to administer along with the 50-item forms. These sets were also balanced in terms of content, and were included to give MSDE flexibility when choosing the final operational items. Finally, each field test form contained a set of 24 common HSA items designed to serve as an external anchor for linking purposes.

The blueprints for the 50-item test design are presented below under the heading, Test Specifications. The basic test design provided information based on specified expectations and the distribution of the number of items for each reporting category. How the specific items were placed throughout the forms was left to the collaborative efforts of the ETS and MSDE content specialists. Construction of the operational forms was based on test blueprints approved by MSDE.

Item Type

The Mod-HSAs consist of SR items only. Each of the four content areas, Algebra, Biology, English, and Government, contained 50 operational items worth a total of 50 points.

Item Modification, Development, Review, and Revision

MSDE oversaw the initial item modification and development. MSDE content and special education specialists worked with Maryland educators to modify existing HSA items and to develop new items written specifically for the Mod-HSA program. These items underwent review and revision at MSDE prior to their submission to ETS for inclusion in the new Mod-HSA item bank.

Once received by ETS, all items were uploaded into the item bank and all graphics and stimulus materials were revised as requested. At this point, all items underwent a series of editorial reviews in accordance with the following procedures:

- Items were edited according to standard rules developed in conjunction with MSDE.
- Items were reviewed for accuracy, organization, comprehension, style, usage, consistency and fairness/sensitivity.
- Item content was reviewed to establish whether the item measured the intended Goal-Expectation-Indicator-Assessment Limit.
- Verification was made that copyright and/or trademark permissions had been obtained for any materials requiring permissions.
- Internal reviews were conducted and historical records established for all version changes.

After ETS performed the required internal reviews, item revision recommendations were submitted to MSDE for their review. Any associated stimulus material, graphic, and/or art was provided as well as information regarding the Goal-Expectation-Indicator-Assessment Limit that each question addressed.

MSDE performed a final review of the items and provided feedback to ETS content specialists. The edits were incorporated into the items. The items were then prepared for review by the Content and Bias/Sensitivity Review Committees.

The Content Review and Bias/Fairness Review Committees, selected by MSDE, conducted the final round of reviews. These committees were composed of diverse groups of Maryland educators. The demographics of the Content Review Committees are summarized in Table 1.1.

Table 1.1 Demographics of Content Review Committees by Content Area

| Content Area | Gender | | Ethnicity | | |
|--------------|--------|--------|------------------|-----------|-------|
| | Male | Female | African American | Caucasian | Other |
| Algebra | 5 | 6 | 2 | 8 | 1 |
| Biology | 2 | 4 | 0 | 6 | 0 |
| English | 0 | 6 | 2 | 4 | 0 |
| Government | 3 | 6 | 2 | 7 | 0 |

The Bias/Fairness Review Committee consisted of one male and nine females; the ethnic composition included two African Americans, six Caucasians, one Hispanic and one Asian.

These committees reviewed each item to ensure that the content: a) accurately reflected what was taught in Maryland schools; b) correctly matched the intended CLG indicator; and c) did not unfairly favor or disadvantage an individual or group. A total of 699 items were reviewed across all four content areas. Of these items, eight (0.01%) were rejected by the Bias/Fairness Review Committee. One hundred and fifty-nine items were accepted with edits (22.7%). In total, the two committees accepted a total of 532 (76.1%) of the 699 Mod-HSA test items

Upon completion of this final round of reviews, MSDE and ETS content specialists conducted another side-by-side meeting to evaluate reviews by the Content Review Committees and the Bias/Fairness Review Committee. The ETS content specialists then made any necessary final edits to the items and/or revisions to the accompanying graphics. The items that survived this process were then eligible for placement on the Mod-HSA forms.

Test Specifications

Tables 1.2 to 1.5 indicate the distribution of items within each reporting category associated with each item type: Mod-HSA items from the 50-item sets, additional Mod-HSA items, and the HSA linking sets. The forms for Algebra, Biology, English, and Government consisted of three sessions administered within a single sitting. Sessions were separated by a short break.

Table 1.2 Algebra Blueprint

| ALGEBRA | | | |
|--|---|---|------------------------------------|
| Reporting Category | Number of Mod-HSA Items in 50-Item Set | Number of Mod-HSA Field Test Items | Number of HSA Linking Items |
| Expectation 1.1 The student will analyze a wide variety of patterns and functional relationships using the language of mathematics and appropriate technology | 13 | 5 - 6 | 6 |
| Expectation 1.2 The student will model and interpret real-world situations, using the language of mathematics and appropriate technology. | 16 | 9 - 10 | 8 |
| Expectation 3.1 The student will collect, organize, analyze, and present data. | 11 | 4 - 5 | 5 |
| Expectation 3.2 The student will apply the basic concepts of statistics and probability to predict possible outcomes of real-world situations. | 10 | 5 - 6 | 5 |
| TOTAL | 50 | 25 | 24 |

Table 1.3 Biology Blueprint

| BIOLOGY | | | |
|---|---|---|------------------------------------|
| Reporting Category | Number of Mod-HSA Items in 50-Item Set | Number of Mod-HSA Field Test Items | Number of HSA Linking Items |
| Goal 1 Skills and Processes of Biology | 10 | 3 | 5 |
| Expectation 3.1 Structure and Function of Biological Molecules | 8 | 2 - 3 | 4 |
| Expectation 3.2 Structure and Function of Cells and Organisms | 8 | 2 | 4 |
| Expectation 3.3 Inheritance of Traits | 9 | 6 - 8 | 4 |
| Expectation 3.4 Mechanism of Evolutionary Change | 6 | 2 - 4 | 3 |
| Expectation 3.5 Interdependence of Organisms in the Biosphere | 9 | 3 - 4 | 4 |
| TOTAL | 50 | 21 | 24 |

Table 1.4 English Blueprint

| ENGLISH | | | |
|--|---|---|------------------------------------|
| Reporting Category | Number of Mod-HSA Items in 50-Item set | Number of Mod-HSA Field Test Items | Number of HSA Linking Items |
| 1: Reading and Literature: Comprehension and Interpretation (RC) Includes the following indicators: 1.1.1; 1.1.2; 1.1.3; 1.2.1; 1.3.3; 3.2.2 | 13 | 5 - 6 | 8 |
| 2: Reading and Literature: Making Connections and Evaluation (RE) Includes the following indicators: 1.1.4; 1.2.2; 1.2.3; 1.2.4; 1.2.5; 1.3.5; 4.1.1; 4.2.1 | 13 | 4 | 6 |
| 3: Writing - Composing (WC) Includes the following indicators: 2.1.1; 2.1.4; 2.2.1; 2.2.2; 2.2.3; 2.2.5; 2.3.1; 2.3.3; 4.3.1 | 13 | 4 - 7 | 6 |
| 4: Language Usage and Conventions (WL) Includes the following indicators: 3.1.3; 3.1.4; 3.1.6; 3.1.8; 3.3.1; 3.3.2 | 11 | 4 - 6 | 4 |
| TOTAL | 50 | 20 | 24 |

Note: Information about the referenced indicators can be found in the Maryland Core Learning Goals for English. The HSA Core Learning Goals documents can be found on the Maryland School Improvement website at <http://www.mdck12.org/assessments/standards/9-12.html>.

Table 1.5 Government Blueprint

| GOVERNMENT | | | |
|--|---|---|------------------------------------|
| Reporting Category | Number of Mod-HSA Items in 50-Item set | Number of Mod-HSA Field Test Items | Number of HSA Linking Items |
| Expectation 1.1 The student will demonstrate understanding of the structure and functions of government and politics in the United States | 14 | 5 | 7 |
| Expectation 1.2 The student will evaluate how the United States government has maintained a balance between protecting rights and maintaining order. | 12 | 7 | 6 |
| Goal 2 The student will demonstrate an understanding of the history, diversity, and commonality of the peoples of the nation and world, the reality of human interdependence, and the need for global cooperation, through a perspective that is both historical and multicultural. | 8 | 4 | 4 |
| Goal 3 The student will demonstrate an understanding of geographic concepts and processes to examine the role of culture, technology, and the environment in the location and distribution of human activities throughout history. | 7 | 3 | 3 |
| Goal 4 The student will demonstrate an understanding of the historical development and current status of economic principles, institutions, and processes needed to be effective citizens, consumers, and workers. | 9 | 6 | 4 |

Item Selection and Form Design

For the May 2008 administration, the MSDE and ETS content specialists worked together to create the field test forms. The Mod-HSA items included in these forms were balanced in terms of content, and were included to give MSDE flexibility in determining the final operational set of items.

The 24 items in the external anchor sets were embedded within the field test forms for each content area in groups of 6 to 8 items within each section of the test. Care was taken to place the HSA items in approximately the same position within the Mod-HSAs as

when these items were originally field tested and parameters were established. More details about the equating design are provided in Section 4.

The general steps completed during the test construction process were:

1. For each content area, both forms were constructed simultaneously to provide the best opportunity to construct parallel forms.
2. Test developers were careful to ensure that the item selections met all content specifications, including matching items to the test blueprint, distribution of keys, and avoidance of clueing² or clanging³.
3. After the 50-item base forms were selected, additional item sets of 20 to 25 items were selected, resulting in 70 to 75 item forms. While the base form and additional item sets were not originally constructed to meet psychometric criteria, they were constructed to meet content criteria. The additional item sets were embedded throughout the base form.
4. External anchor sets of 24 items, representing the Mod-HSA blueprint, were then selected from the HSA item bank. These items, referred to as linking items, were selected to meet content and psychometric criteria. The linking items were embedded in groups of 6 or 8 across the Mod-HSA items, resulting in test forms of 94 to 99 total items.

The test construction process resulted in two field test forms per content area, each containing 94 to 99 items, depending on the subject. Following the administration and review of item analyses, MSDE made a final decision on the set of 50 items to comprise the operational forms for the present and future administrations. These 50 items were selected based on the blueprint and psychometric criteria defined for the Mod-HSA program. The remaining Mod-HSA items and corresponding statistics were sent to the item bank.

² Clueing refers to information within a passage, stimulus, item, graphic, or other test component that allows respondents to select/construct the correct answer to one or more items in an assessment without the knowledge and/or skill targeted by the item.

³ Clanging occurs when an identical or resembling word(s) appears in both the item stem and one or more item distractors.

Section 2. Validity

Validity is one of the most important attributes of assessment quality. Validity refers to the degree to which logical, empirical, and judgmental evidence supports a proposed interpretation or use of a set of scores, and it is one of the most fundamental considerations in developing and evaluating tests (AERA, APA, & NCME, 1999; Messick, 1989). Validity is not based on a single study or type of study; but involves an ongoing process of gathering evidence supporting the interpretation or use of the resulting test scores. The process begins with the test design and continues throughout the entire assessment process, including design, content specifications, item development, psychometric quality, and inferences made from the results.

Mod-HSA items were adapted from banked HSA (SR) items. The development of test content was overseen by a content expert who has a depth of knowledge and teaching experience related to the course in which the Mod-HSA was to be administered. Appropriate content leads who had similar qualifications reviewed the test development work of these individuals.

The constructs measured by each Mod-HSA are described in detail in the Maryland high school curriculum standards (Core Learning Goals, CLGs). All ETS content staff working on test development have been trained in the CLGs. The test blueprint documents presented in Section 1 (see Tables 1.2 to 1.5) were created in collaboration with committees of Maryland educators and were derived from the Maryland goals, expectations, and indicators. The CLGs can be found on the MSDE website at <http://www.mdk12.org>.

Banked items were referenced to a particular instructional standard (i.e., goal, expectation, or indicator). During the internal ETS development process the specific reference was confirmed or changed to reflect changes to the item. When the item went to a committee of Maryland educators for content review, the members of the committee made independent judgments about the match of the item content to the standard it was intended to measure, and evaluated the appropriateness for the age and cognitive ability of students being tested.

As described in Section 1, the process of adapting banked HSA items for use as Mod-HSA items involved simplifying the question format to make items more accessible for special education students. For example, items were modified to reduce reading load and simplify graphics. One answer option was removed from each of the SR items so that students chose from three options instead of four options. The process of selecting and modifying items provided numerous opportunities for the client to review test content and make changes to ensure that the items were aligned with the Maryland content standards.

In addition to the validation documentation gathered and maintained by MSDE, other information in support of the Mod-HSA can be found in the following sections of this technical report:

- Section 3 provides information regarding the item-level analyses used to inform selection of the 50-item operational forms. Descriptions of classical item analyses and differential item functioning, as well as summary tables of item p-values and item-total correlation distributions are presented;
- Section 4 presents information concerning item response theory calibration methods and scaling to align the Mod-HSAs to the HSA scale;
- Section 5 describes the scoring procedures and provides cut score information;
- Section 6 presents information concerning the test characteristics based on classical test theory for the May and Summer administrations;
- Section 7 provides information regarding student characteristics for the May and Summer administrations.

Section 3. Item-Level Analyses: May Administration

Analyses of the field test items were conducted following receipt of the final scored student data files. Item analyses results were examined prior to the selection of operational items. Item-level analyses consisted of classical item analyses and differential item functioning (DIF). Analyses were completed using GENASYS.

As mentioned in the introduction, two groups of students were administered the Mod-HSAs during the May administration. Item analyses and DIF were conducted separately for the *Target* population, students identified as being eligible to take the Mod-HSAs, and for the *Linking* samples that took both the Mod-HSA and the HSA.

Data Files

The data used for the analyses included all valid records available, including students learning English as a second language, students with IEP or 504 plans, and students receiving accommodations. Only records invalidated by the test administrator, and records with five or fewer item responses were excluded from the analysis sample.

For the Target population who could take the Mod-HSAs online or in paper format, data were combined across mode of administration for each form, for all analyses.

Results of the item analyses and DIF analyses were provided to MSDE in Excel files containing item-level statistics, by form, for each content area. The files included blueprint information, classical item statistics, DIF statistics and flags for item statistics outside of the range of criteria approved by MSDE's technical advisors, National Psychometrics Council (NPC). These criteria are described later in this section. Also included in the files was a flag which indicated whether an item had been originally selected as part of the 50-item base form described in Section 1 of this report.

While data provided by the Linking samples were used to select operational items, statistics based on the Target population were also included in the files so that results from the two groups of students could be compared. To assist MSDE in their selection of operational forms, items flagged with statistics outside the range of the criteria for the Linking sample students were highlighted in red. Items with acceptable statistics for the Linking samples but less than desirable statistics for the Target population were highlighted in green and flagged as "Use with Caution." A variable indicating the number of items required for each subscore was also included in the Excel files.

Classical Item Analyses

Classical item analyses involve computing a set of statistics for every item in each form. The statistics provide key information about the quality of the items from an empirical perspective. The statistics estimated for the Mod-HSA items, and associated criteria used to flag items for content specialists' review, are described below.

Classical item difficulty (“p-value”):

This statistic indicates the mean item score expressed as a proportion of the maximum obtainable item score. For SR items, it is equivalent to the proportion of examinees in the sample that answered the item correctly. Desired p-values generally fall within the range of 0.10 to 0.90. Occasionally, items that fall outside this range can be justified for inclusion as an operational item based upon the quality and educational importance of the item content or the ability to measure students with very high or low achievement, especially if the students have not yet received instruction in the content.

The item-total correlation of the correct response option:

This statistic describes the relationship between performance on the specific item and performance on the total test including the item under study. It is sometimes referred to as a discrimination index. For SR items, the item-total correlation is the point-biserial correlation. Values less than 0.10 were flagged for a weaker than desired relationship and requiring careful consideration by MSDE before including them on operational forms. Items with negative correlations can indicate serious problems with the item content (e.g., multiple correct answers, unusually complex content), an incorrect key, or students have not been taught the content.

The proportion of students choosing each response option:

This statistic indicates the percent of examinees selecting each answer option. Item options not selected by any students or selected by a very low proportion of students indicate problems with plausibility of the option. Items that did not have all answer options functioning would require careful consideration by MSDE before including on operational forms.

The point-biserial correlation of incorrect response option with the total score:

These statistics describe the relationship between selecting an incorrect response option for a specific item and performance on the total test including the item under study. Typically, the correlation between an incorrect answer and total test performance is weak or negative. Values

are typically compared and contrasted with the discrimination index. When the magnitude of these point-biserial correlations for the incorrect answer is stronger, relative to the correct answer, the item will be carefully reviewed for content-related problems. Alternatively, positive point-biserial correlations on incorrect option choices may indicate that students have not had sufficient opportunity to learn the material.

Percent of students omitting an item:

This statistic is useful for identifying problems with test features such as testing time and item/test layout. Typically, it is assumed that if students have an adequate amount of testing time, 95% of students should attempt to answer each question. When a pattern of omit percentages exceeds 5% for a series of items at the end of a timed section, this may indicate that there was insufficient time for students to complete all items. For individual items, if the omit percentage is greater than 5% for a single SR, this could be an indication of an item/test layout problem. For example, students might accidentally skip an item that follows a lengthy stem.

The P-values for all of the Mod-HSA items administered are summarized for the Linking samples and for the Target populations in Tables 3.1 and 3.2. The point-biserials for these items and groups are summarized in Table 3.3 and 3.4. Recall that statistics from the Linking samples were used to select the operational items.

In addition, a series of flags was created to identify items with extreme values. Flagged items were subject to additional scrutiny prior to the inclusion of the items in the final calibrations to place the Mod-HSA operational items onto the HSA scale. The following flagging criteria were applied to all Mod-HSA items administered in May 2008:

- *Difficulty Flag*: P-value less than 0.10 or greater than 0.90.
- *Discrimination Flag*: Point-biserial correlation less than 0.10 for the correct answer.
- *Distractor Flag*: Positive point-biserial correlation for incorrect option.
- *Omit Flag*: Percent omitted is greater than 5.

Following classical item analyses, items with poor item statistics were removed from further analyses (refer to Table 3.5). While these items were retained in the Mod-HSA item bank, they have been identified as “Do Not Use.” Table 3.6 presents the number of items that were flagged but retained for further analyses and evaluation. These items were flagged for statistical reasons including extreme p-values; low item-total correlations; and/or high omit rates. Calibration results indicated the items were estimated reasonably, and therefore were not removed from scaling.

Differential Item Functioning

Following the classical item analyses, differential item functioning (DIF) analyses were completed. One goal of test development is to assemble a set of items that provides an estimate of student ability that is as fair and accurate as possible for all groups within the population. DIF statistics are used to identify items that identifiable groups of students with the same underlying level of ability have different probabilities of answering correctly (e.g., females, African Americans, Hispanics). If the item is more difficult for an identifiable subgroup, the item may be measuring something different than the intended construct. However, it is important to recognize that DIF flagged items might be related to actual differences in relevant knowledge or skill (item impact) or statistical Type I error. Subsequent review by content experts and bias/sensitivity committees is required to determine the source and meaning of evident differences.

ETS used the Mantel-Haenszel DIF detection method to assess differential SR item performance. As part of the Mantel-Haenszel procedure, the statistic described by

Holland & Thayer (1988), known as MH D-DIF, was used⁴. This statistic is expressed as the difference between the focal and reference group performance on an item after conditioning on total test score. Negative MH D-DIF statistics favor the reference group and positive values favor the focal group. The classification logic used for flagging items is based on a combination of absolute differences and significance testing. Items that are not significantly different based on the MH D-DIF ($p > 0.05$) are considered to have similar performance between the two studied groups; these items are considered to be functioning appropriately. For items where the statistical test indicates significant differences ($p < 0.05$), the effect size is used to determine the direction and severity of the DIF. The male and white groups were treated as the reference groups for gender and ethnicity, respectively; the female and other ethnic groups were considered the focal groups.

Based on their DIF statistics, items are classified into one of three categories and assigned values of A, B or C. Category A items contain negligible DIF, Category B items exhibit slight or moderate DIF, and Category C items have moderate to large DIF. Negative values imply that conditional on the matching variable, the focal group has a lower mean item score than the reference group. In contrast a positive value implies that, conditional on the matching variable; the reference group has a lower mean item score than the focal group.

There were 16 items flagged for C-level DIF involving one or more of the identified focal groups (i.e., female, African American, American Indian, Asian, Hispanic). The items flagged for C-category DIF included nine Algebra items, one Biology item, two English items and four Government items. These items were retained in the Mod-HSA item bank, and will be reviewed and evaluated to determine their eligibility for future use.

⁴ The formula for the estimate of constant odds ratio is:

$$\hat{\alpha}_{MH} = \frac{\left(\sum_m \frac{R_{rm}W_{fm}}{N_m} \right)}{\left(\sum_m \frac{R_{fm}W_{rm}}{N_m} \right)},$$

where,

R_{rm} = number in reference group at ability level m answering the item right,

W_{fm} = number in focal group at ability level m, answering the item wrong,

R_{fm} = number in focal group at ability level m answering the item right,

W_{rm} = number in reference group at ability level m, answering the item wrong,

N_m = total group at ability level m.

This can then be used in the following formula (Holland & Thayer, 1988):

$$MH\ D\ -\ DIF = -2.35 \ln[\alpha_{MH}] .$$

Section 4. Item Calibration and Test Equating

Item Calibration

All of the items in the May 2008 field test forms were calibrated concurrently using the three parameter logistic (3PL) model and the Linking sample for each subject area. As described in Section 1, this sample consisted of a subset of the May 2008 HSA examinees who also took the Mod-HSA in the same content area to provide data that could be used for linking. All students in the Linking sample took the Mod-HSAs online.

The 3PL model states that the probability that a person with ability θ will respond correctly to item j can be expressed as follows:

$$P(U_j = 1 | \theta) = P_j(\theta) = c_j + \frac{1 - c_j}{1 + e^{-1.7a_j(\theta - b_j)}}$$

where:

- U_j is the response to item j , 1 if correct and 0 if incorrect;
- a_j is the slope parameter of item j , characterizing its discrimination;
- b_j is the threshold parameter of item j , characterizing its difficulty; and
- c_j is the lower asymptote parameter of item j , reflecting the chance that students with very low proficiency will select the correct answer; sometimes called the “pseudo-guessing” level.

A proprietary version of the PARSCALE computer program (Muraki & Bock, 1995) was used to estimate the item parameters.

Initially all item parameters were freely estimated and placed on scale using the Stocking and Lord (1983) procedure. Comparisons of the characteristic curves for the linking and reference parameters after linking revealed some divergence at the lower end of the ability scale. A second calibration run was conducted after fixing the c -parameters of the linking items to their bank values. This approach improved the correspondence between the characteristic curves for reference and linking parameters throughout the full range of ability.

Test Equating

The Mod-HSA forms were linked to the HSA scale using two linking methods. The first involved use of common items, and the second involved use of common persons. Two approaches were planned, so that if one method was not effective, there would be an alternative approach to link the Mod-HSAs to the HSA scale. The equating methods used for each design are described in the following sections.

Linking using the Common Items Design

The 24 anchor items in each form were drawn from the HSA item bank and placed on the field test forms without modification. The linking items were placed in approximately the same positions within the test as when the items were originally field tested, to avoid position effects. The same 24 items were used in both forms administered in each content area.

The linking items had parameters estimated when the field test forms were calibrated. The banked parameters were expressed on the HSA reporting scale. The Stocking and Lord (1983) procedure was used to align the TCCs based on the two sets of parameters and to derive linear constants that could be used to transform the Mod-HSA parameters to the HSA reporting scale.

Linking using the Common Persons Design

Students in the linking samples had taken both a regular HSA and a Mod-HSA assessing the same content area. As a result, two sets of scores were available for the students; an HSA scale score and a Mod-HSA theta estimate generated after the Mod-HSA forms were calibrated.

Linear equipercentile equating was used to find linear transformation values that would minimize the differences between scores on two test forms (Yen & Fitzpatrick, 2006). The process involves using the equipercentile equating procedure to identify corresponding scores on the two forms, one of which is a target form. A linear transformation then is found that minimizes the differences between the scores of the form to be equated and the target form. The transformation is applied to the item parameters and ability estimates associated with the form to be equated to align them with the target score scale.

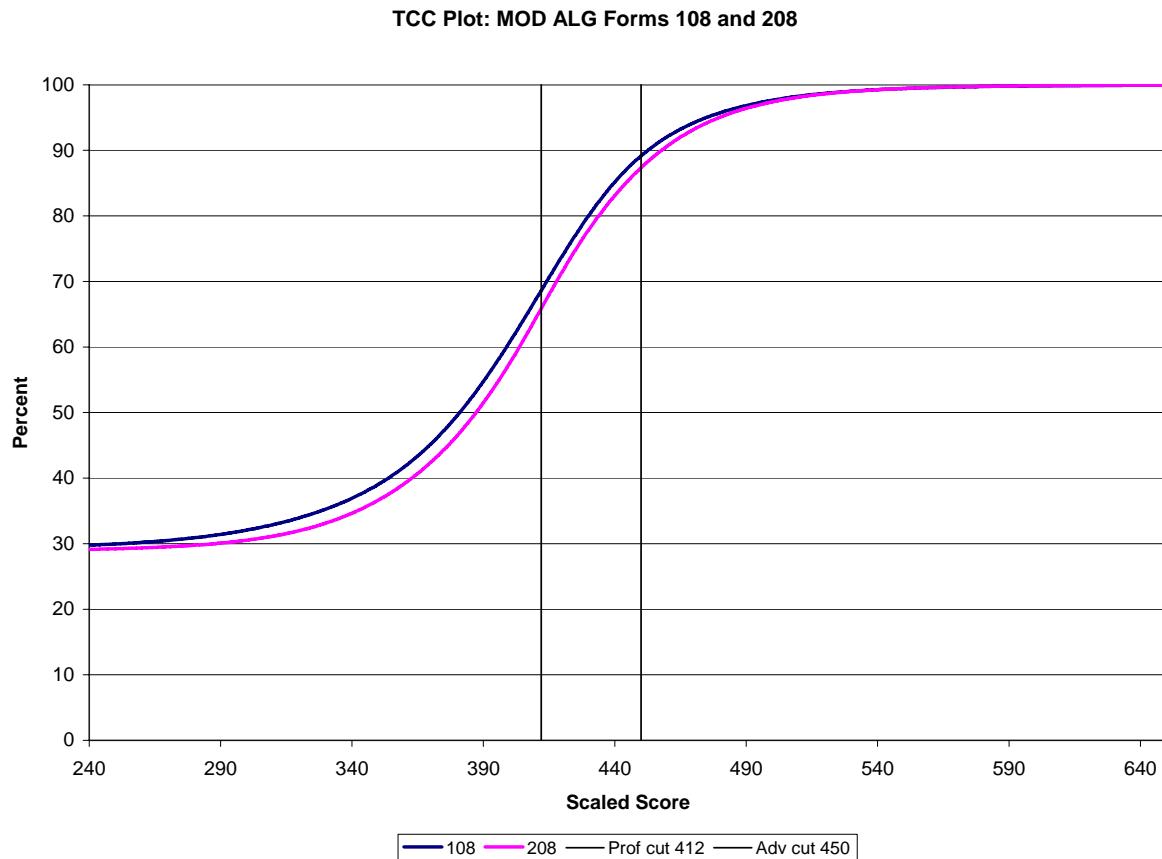

In this case the regular HSA form was the target, so student scores obtained using the Mod-HSAs were aligned to their HSA scale scores. These analyses were completed using *LinEq*, an ETS proprietary software program.

Comparison of Results from the Two Equating Methods

A summary of the equating findings is provided in Appendix C. In general, the two approaches to linking the Mod-HSA to the HSA produced very similar results. The NPC recommended to use the results obtained using the parameters of the common items design and the Stocking and Lord (1983) equating method. One reason for this decision was that IRT equating allows for the removal of misbehaving items; another was that this would allow the same equating method to be used for both the Mod-HSA and the HSA.

Comparison of TCCs and CSEMs

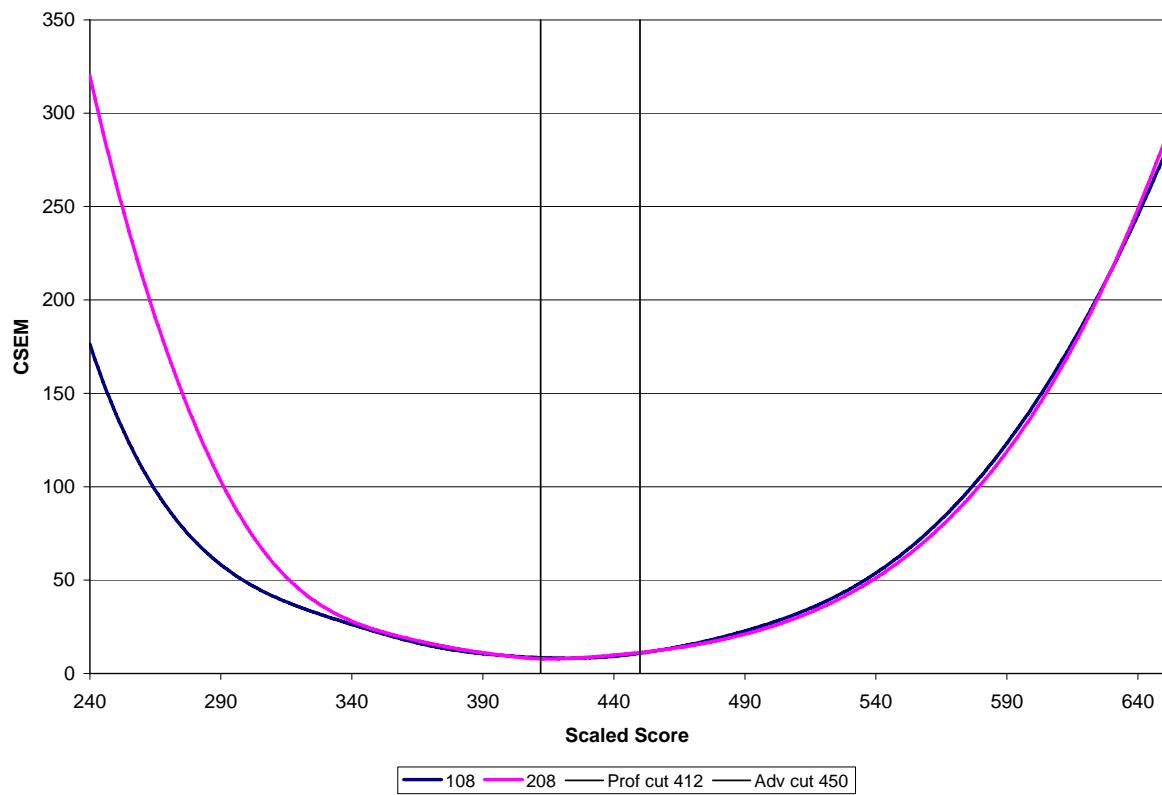

Figures 4.1 to 4.8 present the TCCs and CSEMs, resulting from the Stocking and Lord (1983) equating method, for the two forms in each content area.

Section 5. Scoring Procedures

Scale Scores

The Mod-HSA reporting scale ranges from 240 to 650. This scale was aligned to the HSA scale, which was established in 2003. Scale scores describing total test performance on the Mod-HSA are maximum likelihood estimates (MLEs) obtained using item-pattern (IP) scoring. Subscores are based on raw score to scale score (RS-SS) scoring tables.

When IP scoring with the 3PL model is used, the likelihood equation can have multiple maxima. Therefore, a numerical method was used to find the scale score at the global maximum in the likelihood function. RS-SS scoring tables were obtained by taking the inverse of the TCCs for items contributing to the associated subscores (Yen, 1984).

Since the Mod-HSAs forms were aligned with the HSA scale, the cut-scores established for the HSAs were used to generate performance category (Basic, Proficient, and Advanced) and Pass-Fail classifications for the Mod-HSAs.

Lowest and Highest Obtainable Test Scores

The maximum likelihood procedure under the 3PL model cannot produce reasonable scale score estimates for students with perfect scores or scores below the level expected by guessing. While maximum likelihood estimates are usually available for students with extreme scores other than zero or perfect, occasionally these estimates have very large conditional standard errors of measurement (CSEMs), and differences between these extreme values have little meaning. Therefore, scores were established for these students based on the procedure used for the HSA (refer to Appendix 3.C of the 2004 Technical Report). These values were called the lowest obtainable scale score (LOSS) and the highest obtainable scale score (HOSS). The same LOSS and HOSS values were used for RS-SS tables and the IP scoring. Starting with the summer 2005 administration of the HSA, MSDE decided that the LOSS and HOSS values would be 240 and 650, respectively, for all content areas. Since the Mod-HSA is on the same scale as the HSA, the same LOSS and HOSS values were used.

Cut-Scores

MSDE requested that the Mod-HSAs be aligned with the HSA scales so that the cut-scores established for the HSAs could be applied to the Mod-HSAs. The HSA cut-scores associated with each performance level in the non-English content areas were established

by MSDE in 2003⁵. The HSA English cut-scores were established during a standard setting held in October of 2005.

Two cut-scores were established for the Algebra and English tests, enabling students to be classified as Basic, Proficient, or Advanced. Two cut-scores were needed because the results for these tests are used as the high school mathematics and English/language arts components of Maryland's system of accountability⁶ under NCLB. Prior to the 2007-2008 school year, Biology had only one cut-score. In 2007 two cut-scores were applied to Biology and the results are now used as components of the MSDE accountability system. There is only one cut-score for the Government test; it is used to classify students as Basic or Proficient.

To verify that the cut-scores established for the HSAs were appropriate for the Mod-HSA, a standard setting was conducted in August 2008, using the Mod-HSA student results. The standard setting panels, consisting of Maryland general and special educators, confirmed that the HSA cut-scores were appropriate for the Mod-HSA⁷.

Students eligible to take a Mod-HSA and who entered grade 9 in or after the 2005-2006 academic year, must pass Mod-HSAs or HSAs in all four content areas or achieve an overall combined score of 1602 as part of the requirements for graduation. The Proficient cut-scores are used to determine Pass/Fail classifications. The cut-scores by content area are given in Table 5.1.

Table 5.1 Mod-HSA 2008 Cut-Scores by Content Area

| Content Area | Cut-score | |
|--------------|------------|----------|
| | Proficient | Advanced |
| Algebra | 412 | 450 |
| Biology | 400 | 452 |
| English | 396 | 429 |
| Government | 394 | --- |

⁵ Technical documentation on the standard setting method used to establish the HSA cut-scores is available on the Maryland State Department of Education web site at <http://www.marylandpublicschools.org/msde/divisions/planningresultstest/maryland+standard+setting+technical+reports.htm>.

⁶ Information regarding the system of accountability is available on the Maryland State Department of Education web site at http://www.marylandpublicschools.org/NR/rdonlyres/0146EDA2-5F91-47DD-9A84-16164BDEA25C/18082/Acct_workbook_final_w_table_appendices_r_93008.doc

⁷ Information regarding the standard setting process for the Mod-HSA is available at the MSDE web site http://www.marylandpublicschools.org/NR/rdonlyres/3253C1DD-CA2E-4E64-A066-D6F36EBADF9B/18003/ModHSA_SB_Final.ppt

Section 6. Test Characteristics

The analyses in this section include internal consistency reliability, decision consistency, decision accuracy, and exploratory factor analyses. Results for the May administration are presented for both the Target populations and Linking samples. Results from the Summer administration are presented for each content area by form for the Target population only. Factor analyses were not conducted for the Summer administration.

Reliability

The general concept of reliability concerns the precision of a test score. Of interest is quantifying the degree to which a score will vary from an average result obtained over many testing occasions due to random factors (Haertel, 2006). There are a variety of theories and methods that can be used to estimate reliability.

Classical test theory defines reliability as the proportion of total score variance that is true-score variance. Several different ways of estimating this proportion exist. The estimate of reliability given in this report is Cronbach's alpha (Cronbach, 1951), an internal consistency measure. It is derived from analysis of the consistency of performance over items within a test and provides a lower-bound estimate of a test's reliability. Cronbach's alpha can be expressed as

$$\alpha = \frac{n}{n-1} \left[1 - \frac{\sum_{i=1}^n \sigma_i^2}{\sigma_x^2} \right],$$

where n is the number of items, σ_i^2 is the variance of scores on the i -th item, and σ_x^2 is the variance of the total score (sum of scores on the individual items).

Values for Cronbach's alpha were calculated for each test form, test group, and selected subgroups. The results for the reliability analyses are presented along with other summary statistics in Tables 7.12 to 7.23 of Section 7. The tables show that the reliability coefficients for the May results ranged from 0.71 to 0.79 for the Target populations and from 0.86 to 0.89 for the Linking samples; the reliability coefficients for the Summer results ranged from 0.69 to 0.80.

Decision Accuracy and Decision Consistency

The accuracy of decisions based on specified cut-scores was assessed for Reliability of Classification using the ETS computer program RELCLASS. RELCLASS provides two statistics that describe the reliability of classifications based on test scores (Livingston & Lewis, 1995). More specifically, information from an administration of one form is used to estimate the following:

- 1) Decision Accuracy describes the extent to which examinees are classified in the same way as they would be on the basis of the average of all possible forms of a test. Decision accuracy answers the question: How does the actual classification of test takers, based on their single-form scores, agree with the classification that would be made on the basis of their true scores, if their true scores were somehow known?
- 2) Decision Consistency describes the extent to which examinees are classified in the same way as they would be on the basis of a single form of a test other than the one for which data are available. Decision consistency answers the question: What is the agreement between the classifications based on two non-overlapping, equally difficult forms of the test?

RELCLASS estimates decision accuracy using an estimated joint distribution of reported performance level classifications on the current form of the test and the performance level classifications based on an all-forms average (true score). RELCLASS estimates decision consistency using an estimated joint distribution of reported performance level classifications on the current form of the test and performance level classifications on an alternate (parallel) form. In each case, the proportion of performance level classifications with exact agreement is the sum of the entries in the diagonal of the contingency table representing the joint distribution.

RELCLASS results were calculated using student scale scores derived from item pattern (IP) score distributions, for each form and content area. In four cases, the RELCLASS program would not converge due to the nature of the data (e.g., small sample sizes, and/or skewed performance distributions). The four exceptions were: Biology, Form 208 taken by the May Target population, Government, Form 208 taken by the May Linking sample, and Biology and English, Forms 308 taken by the summer Target populations. RELCLASS models unimodal data, and the IP scores for these tests did not appear to match this model. As an approximation to the RELCLASS results based on IP scoring, decision accuracy and consistency analyses for these four forms were obtained using raw score-to-scale score conversion tables. In all but one case (Biology, Form 308 taken by the Summer Target population) RELCLASS was able to converge using these RS-SS scores. Comparisons between the consistency and accuracy results obtained using IP and RS-SS scoring for the other HSA and Mod-HSA forms indicated that the two approaches typically produced findings that differed by 1% or less. However, because operational scores are based on IP scoring, results based on RS-SS should be regarded as an approximation.

Results are provided in Tables 6.1 to 6.12 for each group of students by form and content area for the May administration and by content area for the Target population of the Summer administration. Results from the Summer administration are provided for Form 308 only; very small numbers of students took Form 408. The tables show decision accuracy values which describe the agreement between classifications based on an observable variable (scores on one form of a test) and classifications based on an

unobservable variable (the test takers' true scores). For Target students in the May administration, decision accuracy values ranged from 0.85 to 0.89 across all performance levels and content areas and from 0.82 to 0.91 for the Proficient and Advanced classifications in Algebra, Biology and English. For Linking students in the May administration, decision accuracy values ranged from 0.74 to 0.86 across all performance levels and content areas and from 0.86 to 0.90 for the Proficient and Advanced classifications in Algebra, Biology and English. For Target students in the Summer administration, decision accuracy values ranged from 0.87 to 0.90 across all performance levels for Algebra, English, and Government, and from 0.82 to 0.91 for the Proficient and Advanced classifications in Algebra and English.⁸

Decision consistency values describe the agreement between classifications based on two variables (scores on the form students have taken and a parallel form of the same test that is not administered to the students). For Target students in the May administration, decision consistency values ranged from 0.79 to 0.85 across all performance levels and content areas and from 0.82 to 0.87 for the Proficient and Advanced classifications in Algebra, Biology and English. For Linking students in the May administration, decision consistency values ranged from 0.68 to 0.82 across all performance levels and content areas and from 0.81 to 0.86 for the Proficient and Advanced classifications in Algebra, Biology and English. For Target students in the Summer administration, decision consistency values ranged from 0.79 to 0.85 across all performance levels for Algebra, English, and Government, and from 0.82 to 0.87 for the Proficient and Advanced classifications in Algebra and English.

Note that in all cases the decision accuracy indices are somewhat larger than the decision consistency indices. This is due to differences in the estimation procedures. The estimation procedure for decision accuracy includes a random component on one of the two variables, whereas in estimating decision consistency each variable includes a random component (Livingston & Lewis, 1995).

⁸ RELCLASS did not converge for Biology for the Summer Target population.

Exploratory Factor Analysis

To investigate the dimensionality of the Mod-HSA operational forms created after the May administration, exploratory factor analyses were conducted at the item level for each 50-item operational form created after the May 2008 test administration. The software program MPLUS (Muthén & Muthén, 2007) was used to generate tetrachoric correlations that were then read into the program for the analyses. Two groups of students, the Target populations and the Linking samples, were analyzed separately. The estimator used in these exploratory analyses was a weighted least-squares with mean and variance adjustment (Muthén, DuToit, & Spisic, 1997). This estimator was specifically designed for the analysis of ordered categorical data. Solutions were rotated by Quartimin methods, because the factors were expected to be correlated.

The percentage of score variance accounted for by each factor having an eigenvalue greater than 1.0 is shown in Tables 6.13 to 6.20 for each form. The decision to include only eigenvalues greater than 1.0 follows the Kaiser-Guttman rule (Kaiser, 1960). Scree plots (Catell, 1966) for each form are given in Figures 6.1 to 6.16 for the first 50 factors extracted. The scree plot involves plotting the eigenvalues of the factors extracted in order of magnitude from high to low. The plot is examined for a point at which the decrease in eigenvalues levels off. Factors prior to this point are considered important because of the variance they explain. Factors at and beyond this point add relatively little information.

Examination of the plots and tables for the Linking samples shows that the eigenvalues for the first factors ranged from about 12.0 to 15.6 across forms and subject areas, and these first factors accounted for 24% to 31% of the variance. The eigenvalues for the second and subsequent factors were no greater than about 2.0, and these factors accounted for about 2% to 5% of the remaining variance. Results for the two forms taken by the Linking samples were very similar across forms. The sizable amount of variance accounted for by the first factor indicates a large first factor; confirmatory factor analyses

or a study of the essential dimensionality of the data for the Linking samples could be used to assess the fit of a single factor model to the data.

With regard to the Target populations, the first factor results tended to be about half of those obtained for the Linking samples. Specifically, the eigenvalues for the first factors ranged from about 5.5 to 7.0, and this factor accounted for about 11% to 14% of the variance. Thus, for the Target populations a much smaller first factor was found. Like the Linking samples, the second and subsequent factors had small eigenvalues and accounted for 4% or less of the remaining variance.

The lower eigenvalues and percentages of score variance accounted for by the first factor in the Target populations appears to be a product of the difficulty of the Mod-HSA items for students in the Target populations. Table 6.22 shows that for the Linking group the mean item p-values were in the low 0.70's, a moderate degree of difficulty. For the Target populations, Table 6.23 shows that they were in the high 0.40's, on average. The Mod-HSA items are multiple-choice items with three answer choices; therefore the item p-values could reflect a considerable amount of guessing.

Very difficult items discriminate less well than do moderately difficult items and introduce more error because of increased guessing. As shown in Tables 6.23 and 6.24, the Mod-HSA item point-biserials were considerably lower for the Target population than they were for the Linking sample. Also the internal consistency results were notably lower: for the Linking samples, internal consistency ranged from 0.86 to 0.89 across subject areas, whereas for the Target populations it ranged from 0.71 to 0.79. Comparison of the tetrachoric correlations read into the factor analyses and summarized in Table 6.25 also shows that the item intercorrelations for the Target population were quite low and about half the size of those observed for the Linking sample, on average. Presumably as achievement in the Target populations improves, item discrimination, internal consistency and the item intercorrelations will improve concomitantly.

Section 7. Student Characteristics

Student characteristics include demographic distributions and summary statistics. The results are provided for both the Target population and the Linking sample for each content area for the May administration⁹ and for the Target population for the Summer administration.

Demographic Distributions

The demographic characteristics of all students that took the Mod-HSAs during the May administration are provided in Tables 7.1, 7.3, 7.5 and 7.7 for Algebra, Biology, English, and Government, respectively. The demographic characteristics of the students taking the Mod-HSAs during the Summer administration are provided in Tables 7.2, 7.4, 7.6 and 7.8 for Algebra, Biology, English, and Government, respectively. As a comparison, the results from the corresponding administrations of the HSAs are also provided. For both administrations, information is provided by form (i.e., 108, 208, both forms combined; 308, 408, both forms combined) and by gender and ethnicity. The results from online and paper test-takers were analyzed together.

The number of students taking the Mod-HSAs during the May administration ranged from 2,012 for the Biology test to 2,720 for the Algebra test for the Target population; the sample sizes ranged from 1,947 for the English test to 3,144 for the Biology test for the Linking sample. Similar numbers of students took each form, within each group and content area.

For the Target population, about 66 percent of the students were male. The ethnicity breakdown included approximately 62 percent African American, 28 percent White, 8 percent Hispanic, 1 percent Asian/Pacific Islander and less than 1 percent American Indian. The gender and ethnicity percentages were consistent across content area.

For the Linking sample, the male to female ratio was approximately equal. The ethnicity breakdown included approximately 60 percent White, 30 percent were African American, and the remaining 10 percent coming from the Hispanic and Asian/Pacific Islander groups. The gender and ethnicity percentages were comparable across content areas.

The number of students taking the Mod-HSAs during the Summer administration ranged from 65 for the Government test to 98 for the Algebra test. Approximately 69 percent of the students were male, with ethnicity percentages similar to the May Target populations.

⁹ In this section, results for the May Target populations are presented before the Linking samples because the Mod-HSA was designed for the Target populations.

Summary Statistics

Students' scale score means and standard deviations are presented in Table 7.9 for each content area and student group from the May administration and for each content area from the Summer administration.

Table 7.9 Mean Scale Scores by Content and Group

| | May - Target Population | | | May - Linking Sample | | | Summer | | |
|------------|-------------------------|--------|-------|----------------------|--------|-------|--------|--------|-------|
| | N | Mean | SD | N | Mean | SD | N | Mean | SD |
| Algebra | 2,720 | 359.88 | 49.54 | 2,513 | 420.32 | 36.69 | 98 | 367.34 | 45.90 |
| Biology | 2,012 | 359.93 | 48.30 | 3,144 | 419.56 | 39.62 | 69 | 365.94 | 44.07 |
| English | 2,532 | 353.34 | 42.49 | 1,947 | 407.72 | 39.67 | 79 | 350.00 | 42.76 |
| Government | 2,270 | 357.00 | 49.58 | 2,249 | 423.97 | 49.75 | 65 | 365.49 | 47.94 |

Table 7.10 presents the percentages of students classified as Passing for the Target population and the Linking sample from the May administration and for the Target population from the Summer administration. Students are identified as passing if they obtain a scale score at or above the Proficient cut-score (see Table 5.1). As would be expected, the passing rates for the Linking samples were much higher than those for the Target population.

Table 7.10 Passing Percentages by Content and Group

| | May Target Population | May Linking Sample | Summer |
|------------|-----------------------------|--------------------------|--------|
| Algebra | 9.85 | 65.70 | 7.14 |
| Biology | 15.95 | 74.87 | 18.84 |
| English | 10.47 | 67.39 | 7.59 |
| Government | 19.82 | 81.15 | 20.00 |

Results from the Algebra, Biology, and English tests are used in the MSDE AYP reports as required under the NCLB Act for the 2007-2008 school year. Table 7.11 shows the percentages of Algebra, Biology, and English students classified as Basic, Proficient, or Advanced. As shown in the table, for the May administration between 84 and 90 percent of the students in the Target population were classified as Basic across content areas. In contrast, between 25 and 34 percent of students in the Linking samples were classified as Basic across the content areas. For the Summer administration, between 81 and 93 percent of students were classified as Basic across content areas.

Table 7.11 Percentages of Students Classified as Basic, Proficient or Advanced, by Content and Group

| | May - Target Population | | | May - Linking Sample | | |
|------------|-------------------------|---------|---------|----------------------|---------|---------|
| | Algebra | Biology | English | Algebra | Biology | English |
| Basic | 90.15 | 84.05 | 89.53 | 34.30 | 25.13 | 32.61 |
| Proficient | 9.52 | 15.85 | 10.27 | 49.86 | 57.82 | 43.25 |
| Advanced | 0.33 | 0.10 | 0.20 | 15.84 | 17.05 | 24.14 |
| | Summer | | | | | |
| | Algebra | Biology | English | | | |
| Basic | 92.86 | 81.16 | 92.41 | | | |
| Proficient | 6.12 | 18.84 | 7.59 | | | |
| Advanced | 1.02 | 0.00 | 0.00 | | | |

Summary statistics for all students and for subgroups based on gender and ethnicity are presented by group and content area in Tables 7.12 through 7.23. For each administration, information is provided for each form individually and the two forms combined. As noted previously, results from the paper and online versions of Form 108 of the May administration of the Mod-HSAs were pooled for the Target population. As a comparison, the results from the May 2008 administration of the HSAs are also provided.

The tables include the number of students tested for whom valid scores were available, mean scale scores, standard deviations of scale scores, and reliabilities. Note that the overall reliabilities were lower for the Target population (range of 0.71 to 0.79) than for the Linking samples (range of 0.86 to 0.89). Histograms of the scale score distributions are presented in Appendix D. The distributions for the Target population were negatively skewed due to the sizeable numbers of students with scores at the LOSS.

The tables show that within each group of test-takers the means and standard deviations of students' scores were quite similar across forms for the May administration. Students in the Linking sample performed better than students in the Target population for all content areas, as would be expected. For the Summer administration, the majority of students took Form 308.

As can be seen in Tables 7.12, 7.15, 7.18 and 7.21, a consistent trend was found across ethnic groups and content areas for the Target students in the May administration. White students scored higher than Hispanic students, who in turn scored higher than African American students. There were insufficient numbers of examinees to report mean scale scores for Asian/Pacific Islander and American Indian students. For the Linking students, Asian/Pacific Islander and White students tended to perform better than African American and Hispanic students across content areas (Tables 7.13, 7.16, 7.19 and 7.22). There were insufficient numbers of examinees to report mean scale scores for American Indian students.

Note 1: Table entries in bold font were identified as having less than desirable statistics according to the flagging criteria described in Section 3.

Note 2: Some field test items appeared on both Form 108 and Form 208; statistics for these items are shown in Form 108 of the table, for both forms combined.
